ABSTRACT
Collaboration is key to safety and efficiency in Air Traffic Control. Legacy paper-based systems enable seamless and non-verbal collaboration, but trends in new software and hardware for ATC tend to separate controllers more and more, which hinders collaboration. This paper presents a new interactive system designed to support collaboration in ATC. We ran a series of interviews and workshops to identify collaborative situations in ATC. From this analysis, we derived a set of requirements to support collaboration: support mutual awareness, communication and coordination, dynamic task allocation and simultaneous use with more than two people. We designed a set of new interactive tools to fulfill the requirements, by using a multi-user tabletop surface, appropriate feedthrough, and reified and partially-accomplishable actions. Preliminary evaluation shows that feedthrough is important, users benefit from a number of tools to communicate and coordinate their actions, and the tabletop is actually usable by three people both in tightly coupled tasks and parallel, individual activities. At a higher level, we also found that co-location is not enough to generate mutual awareness if users are not engaged in realistic tasks.

SYSTEM REQUIREMENTS
Based on an analysis of collaborative situations in ATC, we devised a set of requirements for our system. Our primary design goal was to foster seamless collaboration by requiring less explicit communication and fewer coordination acts. Our main assumption is that better collaboration will yield benefits in terms of capacity and safety. More precisely, the system should…

- … enable users to inform the systems with their clearances, which is not possible with current, paper-based systems [3].
- … allow more than two users to interact simultaneously with it. This should allow capacity increases since multiple users will be able to handle tasks concurrently (parallelization)
- … foster mutual awareness. Safety should increase because users will have more means to be aware of teammates’ activity and more means to detect problems (more eyeballs).
• foster communication and coordination. This should improve both safety (knowledge of teammate actions) and capacity (less latency).
• foster dynamic task allocation. Capacity should increase because users will be able to pick up new tasks to be done as soon as they have completed existing tasks (workload balancing).

SYSTEM DESIGN
The requirements can be fulfilled if users are aware of tasks to be done, or are able to evaluate workload of their colleague. In addition, it can only be done if any user is allowed to interact with any representation or tools while the other user is engaged in another task. We used a shared, multi-touch, multi-users surface as the basis of our system. Shared surface are supposed to exhibit these properties: users are close to each other, and they enable interacting simultaneously if designed appropriately. We devised the following guidelines to design interactive tools so that they support collaboration:
• Reify actions into objects. Since objects lie on the table, their manipulation may enable accountability [1]; furthermore, they can be passed around and allow for task reallocation.
• Enable partial accomplishment of actions. An action can be separately prepared, checked and accomplished, possibly by different users, thus offering seamless workload allocation.
• Provide as much as feedback as possible. Since activities must be accountable, it is important that appropriate feedback provide an opportunity for teammotes to observe one another’s actions.

We also used several guidelines from tabletop and CSCW literature (orientation [2], territoriality [5], tabletop [1], direct collaboration [1] and coupling [1]). In the following, we mention the guidelines that we applied. We chose not to prevent inter-controller conflicts using technical features; instead, we relied on social norms. We designed several software tools, such as layout-free, orientable strips, editors, Post-it, an extrapolation tool, a timeline, several feedthrough, delayed audio annotation etc.

PRELIMINARY EVALUATION
We have conducted four experiments to evaluate our design choices. The experiments were qualitative and involved a limited number of subjects and trials. As such, they yielded preliminary results only; however, we did make several useful observations. The experiments were not meant to test whether our system is better than current systems in terms of capacity or safety. Rather, they test to what extent the first three requirements we listed above (more than two users, mutual awareness, communication, coordination, dynamic task allocation) are fulfilled. Preliminary evaluation shows that feedthrough is important, users benefit from a number of tools to communicate and coordinate their actions, and the tabletop is actually usable by three people both in tightly coupled tasks and parallel, individual activities. At a higher level, we also found that co-location is not enough to generate mutual awareness if users are not engaged in realistic tasks.

ACKNOWLEDGMENT
The project was funded by Eurocontrol Experimental Center under grant EEC A06/12013BE.
